SUMMARY
Introduction/Objective
Maxillary or mandibular retrognathism are common dentofacial deformities treated by combined orthodontic-surgical treatment. Surgical maxillary or mandibular advancement changes the position and strain of surrounding structures, which may also affect pharyngeal airway dimensions.

The aim of this study was to evaluate and compare three-dimensional pharyngeal airway space changes in patients treated with maxillary advancement and those treated with mandibular advancement.

Methods
The sample consisted of 25 patients – 12 treated with maxillary advancement and 13 with mandibular advancement surgery. Nasopharyngeal (NP) volume, oropharyngeal (OP) volume, and the area of maximum constriction (AMC) in the OP were measured on cone beam computed tomography scans (2 mA / 120 kV / 12” FOV) taken before and at least three months after surgery. Paired samples t-test was used for analyzing statistical significance of changes (p ≤ 0.05).

Results
Postoperative OP and NP volumes, as well as the AMC, increased insignificantly in both groups.

Conclusion
Results suggest that mono-maxillary surgical advancement of the maxilla or the mandible increases pharyngeal airway dimensions.

Keywords: Cone Beam CT; mono-maxillary advancement surgery; pharyngeal airways

INTRODUCTION

Dentofacial deformities are handicapping deviations that compromise patients’ facial features, masticatory function, and pharyngeal airway space (PAS). Since orthodontic treatment alone rarely yields satisfactory results in these patients, orthognathic surgery for repositioning the jaws is usually recommended. Surgical correction changes the position and strain of surrounding structures, therefore improving facial esthetics and occlusion. Moreover, surgery may also affect the dimensions of the oral and nasal cavities, as well as the PAS dimensions, hence improving or impairing breathing [1–5].

Class II and Class III are common dentofacial deformities treated by combined orthodontic-surgical treatment. Class II deformity caused by mandibular retrognathism is treated with a combination of orthodontics and mandibular advancement, most commonly achieved by bilateral sagittal split osteotomy [6]. Class III deformity caused by maxillary retrognathism is treated with a combination of orthodontics and maxillary advancement, which makes up about one half of Class III skeletal deformity treatments [7].

The aim of this study was to analyze and compare three-dimensional (3D) pharyngeal airway changes in orthodontic-surgical patients treated with maxillary advancement and in those treated with mandibular advancement.
natural head posture, teeth at maximum intercuspation and at the end of the exhalation period when the patient was not swallowing. Scanning time was 9.6 seconds.

InVivo Dental Software (Anatomage Inc., San Jose, CA, USA) was used to analyze DICOM (Digital Imaging and Communication in Medicine) images. The images were first oriented using the Patient Orientation tool in the Section View according to the axial, sagittal, and coronal slices. The midsagittal plane was determined according to the foramen incisivum on the axial slice (Figure 1a); the palatal plane was adjusted to coincide with the True Horizontal Plane on the sagittal slice (Figure 1b); infraorbitalis points were aligned on the coronal slice (Figure 1c). The images were further processed in the Volume Render View section, by putting them in greyscale view, setting Reconstruction to Maximum Intensity and moving them upward or downward with the Patient Orientation tool in order to overlap the palatal plane with the central horizontal line of the grid. Airway volumes were calculated in the Volume Render View. The images were kept in greyscale view and reoriented to Top View. Reconstruction was set back to Volume Rendering and images were inverted, opacity reduced until the internal structures became visible and unnecessary parts were removed with the Sculpting Tool. Opacity was increased and brightness and contrast were reset after isolating the desired airway in order to obtain a solid airway before calculating the volume.

**Nasal passages**

For the calculation of the nasal passage (NP) airway volume, inferior border of the NP was determined by the horizontal line through the palatal plane (Figure 2a), and the superior border was determined by moving the axial reference plane on the sagittal slice until noting on the axial slice that it has reached the point where the nasal septum first touches the posterior wall of the pharynx (Figure 2b). The superior-to-inferior border distance was measured with the Distance Measuring Tool on the sagittal slice in the Section View. The 3D Volume Clipping Tool was used for cutting the airway along the axial plane in the Volume Render View. Scrolling the mouse wheel moved the clipping plane where needed until it coincided with the inferior NP border. The distance between the superior and inferior border transferred from the Section View was marked using the Distance Measuring Tool and the part above the superior NP border was removed with the Clipping Tool. After reorientation to Top View, maxillary sinuses were clipped from the final NP volume. The remaining borders were determined by the software since we used automatic segmentation for measuring all volumes, i.e. the Volumetric Measuring Tool, which calculates and displays volume measurements in cubic millimeters and cubic centimeters.

**Oropharyngeal airways**

For the calculation of the oropharyngeal passage (OP) airway volume, inferior border was determined by the horizontal line through the most of the antero-inferior point of the second cervical vertebrae (Figure 2c), and the horizontal line through the palatal plane was used as the superior border (Figure 2a). The NP airway volume view was flipped to the opposite side, making the palatal plane the superior border. The distance between the superior and inferior border transferred from the Section View was marked using the Distance Measuring Tool and the part below the inferior border was cut using the Sculpting Tool. The Volumetric Measuring Tool was used for obtaining the OP volume value.

**Area of maximum constriction in the oropharyngeal airways**

The point of maximum constriction in the pharynx was determined on the sagittal slice by moving the axial reference
plane on the corresponding axial slice. The area of maximum pharyngeal constriction was measured on the axial slices using the Area Measuring Tool.

### Cephalometric analysis

Cephalograms were generated from the DICOM files and analyzed using the Dolphin Imaging software version 11 (Dolphin Imaging, Chatsworth, CA, USA). SNA, SNB, and ANB angles and A-Nperp and B-Nperp linear measurements were used for determining sagittal jaw positions and relationships.

This methodology has previously been proven successful [10, 11, 12]. All measuring was done and re-tested by an experienced operator (NLjS) trained by an expert in the field (JMP).

### Ethics

The images used were pre-existing, taken as a part of the standard diagnostic procedure. All the patients signed the informed consent form allowing the use of their records for research and publication purposes. The Human Research Ethics Committee of the School of Dental Medicine of the University of Belgrade approved this research (resolution number 36/20 from December 14, 2009).

### Statistical analysis

The obtained data was organized and descriptive statistics [means, standard deviations and ranges for pretreatment (T1) and post-treatment (T2) records] was done using Microsoft Office Excel 2010 (Microsoft Corporation, Redmond, WA, USA). Detailed statistical analysis was performed in the SPSS software Version 12 (SPSS Inc., Chicago, IL, USA). The intraclass correlation coefficient was used for determining intra-operator reliability for each measurement. Since the Kolmogorov–Smirnov test revealed the normality of distribution for all data, parametric tests were employed. Statistical significance of changes between T1 and T2 was analyzed with the paired-samples t-test. The level of significance was set at $p < 0.05$.

### Results

The intraclass correlation coefficient values revealed high reproducibility and reliability of all parameter measurements ($r > 0.95$).

Cephalometric measurements and mean ages at T1 and T2 are presented in Table 1 for both groups. Pharyngeal airway measurements are shown in Table 2. Postoperative volumes of the OP and NP, as well as the AMC, increased in both groups without statistical significance (Table 2).

NP volume distribution before and after surgery is presented in Figure 3 for group A and in Figure 4 for group B. OP volume distribution before and after surgery in presented in Figure 5 for group A and in Figure 6 for group B. AMC values distribution is shown in Figure 7 for group A and in Figure 8 for group B.

### Discussion

Orthognathic surgery changes the position and strain of the surrounding structures, which affects the location and

tension of connected tissues and dimensions of the oral and nasal cavities and the PAS [2]. The amount and direction of skeletal movement determines the quantity of PAS dimension changes [1, 2, 5].

The objective of this study was to evaluate PAS changes in patients treated with surgical maxillary advancement and in those treated with surgical mandibular advancement. All patients had CBCT scans taken before and after surgery as a part of the standard diagnostic and treatment planning procedure, which enabled us to preform detailed analysis of the pharyngeal airways using the DICOM sets of images [13].

Looking at the results of the study, we can clearly see that both nasopharyngeal and oropharyngeal volumes, as well as the area of maximal constriction in the pharynx increased in both groups of our sample, i.e. after maxillary or mandibular advancement. However, these changes lacked statistical significance.

Several authors have investigated the effect of mandibular advancement on pharyngeal airway dimensions using either CBCT images or lateral cephalograms. Kochel et al. [14], using CBCT images, found significant increase in the total pharyngeal airway volume five weeks after mandibular advancement, the increase being most pronounced in the lower third of the PAS. The increase in the pharyngeal area was most evident at the level of the soft palate, and changes were more noticeable in the sagittal dimension, again especially in the lower third of the PAS. Hernández-Alfaro et al. [15] also analyzed CBCT scans of patients treated with mandibular advancement and found an increase in airway volumes after surgery. Dalla Torre et al. [16] reached a similar conclusion by analyzing both

lateral cephalograms and CBCT images of patients before and after surgery. They noticed significant increase in both 2D and 3D pharyngeal airway measurements six to eight months after mandibular advancement. Another study done on lateral cephalograms also found an increase in PAS dimensions [17]; however, Eggensperger et al. [18], who followed patients for 12 years after surgery and analyzed their lateral cephalograms, found that mandibular advancement alone did not increase pharyngeal airway dimensions in the long term. The main drawback of that study was the fact that they had used lateral cephalograms, which do not give us enough information regarding the PAS dimensions, namely one of the most important aspects, the area of pharyngeal constriction, can only be analyzed on axial slices of CBCT or CT images. In their overview of systematic reviews on the topic of the effect of mandibular advancement on pharyngeal airways, Tan et al. [19] concluded that more evidence was needed in order to draw conclusions related to the effect of mandibular advancement on pharyngeal airways.

When it comes to the connection between maxillary advancement and PAS dimension changes, not much has been published to date. Hernández-Alfaro et al. [15] found an increase in PAS volumes after analyzing CBCT scans of patients treated with maxillary advancement. However, this increase was less pronounced compared to that recorded in the group treated with mandibular advancement.

The increase in pharyngeal airway dimensions after mono-maxillary surgical advancement of the mandible or of the maxilla is especially important for patients suffering from obstructive sleep apnea syndrome (OSAS). The OSAS is a breathing-related disorder that occurs during sleep and is commonly associated with a compromised PAS and an increase in upper airway collapsibility [20]. It is a common medical condition in the general population nowadays, and we are often challenged by the potential link between pharyngeal airway dimensions and the OSAS in our patients [21, 22]. Therefore, the assessment of the PAS is becoming an important part of the diagnostic procedures in orthodontics and maxillo-facial surgery, and is consequently affecting treatment planning. The most common treatment procedures for the OSAS are continuous positive air pressure, mandibular advancement devices, and maxillo-mandibular advancement surgery [23, 24, 25]. The fact that the PAS dimensions have increased even after mono-maxillary mandibular or maxillary advancement is encouraging. Nevertheless, we must always take into consideration the underlying dentofacial deformity when planning treatment.

Considering the 3D nature and all the advantages of CBCT scans, it is clear why they have already replaced lateral cephalograms as the diagnostic tool of choice for analyzing the pharyngeal airways. However, we are still facing certain limitations of these tools, such as the lack of normative 3D values for pharyngeal airway structures and standardized protocols for obtaining images, as well as the fact that software reliability and operator training and experience play a role [26]. The results of this study would have been more significant if we had the control group of patients with the same pathology, who did not undergo orthodontic-surgical treatment. However, it would not have been ethical to put them through all the testing and expose them to CBCT scanner radiation just so normative data could be collected. Moreover, larger samples would also have been helpful. Nevertheless, CBCT scanning before and especially after orthognathic surgery is still not a standard procedure for all orthodontic-surgical patients, which limits the number of available datasets. The authors are planning to conduct further studies on larger samples in the foreseeable future.

CONCLUSION

The results of this study suggest that mono-maxillar advancement of the mandible or of the maxilla increases both the OP and NP volumes, and the areas of maximal contraction in the pharynx. Larger samples and post-revisionary records are needed in order to obtain better evidence regarding the effect of these procedures on the PAS.

САЖЕТАК
Увод/Циљ Ретрогнатизам горње вилице и ретрогнатизам доње вилице су чести дентофацијални деформитети, који се лече комбиновано ортодонтско-хируршком терапијом. Хируршко померање горње или доње вилице унапред менја положај и напетост околних структура, што такође утиче на димензије фарингеалних ваздушних путева.
Циљ истраживања био је да се процене и упореде тродимензионалне промене фарингеалних ваздушних путева код болесника лечених хируршком корекцијом горње или доње вилице унапред.
Методе Узорак истраживања састојао се од 25 болесника – 12 лечених хируршком корекцијом горње вилице и 13 лечених вилицом доње вилице унапред. Запремни назофаринкса и орофаринкса и површине најужег дела фаринкса су мерене на CBCT снимцима (2 mA / 120 kV / 12° FOV) направљеним пре и бар три месеца после хируршке корекције. Статистичку значајност промена је анализована т-тестом за упарене узорке (p ≤ 0,05).
Резултати Запремне фарингеалне ваздушне путеве након хируршке корекције горње вилице унапред су значајно веће у односу на претходне мере (p ≤ 0,05). Запремне фарингеалне ваздушне путеве након хируршке корекције доње вилице унапред су у односу на претходне мере не значајно измене.
Закључак Резултати показују значајно покачење фарингеалних ваздушних путева након хируршке корекције ортопедије вилице унапред. Ово је значајно за хируршку практику и показује значајну утицај на ваздухопитање узроковано стоматолошким интервенцијама.
Кључне речи: CBCT, мономаксиларна ортогнатска хирургија, фарингеални ваздушни путеви
