The aim of this study is to evaluate efficacy of radiofrequency on early clinical outcomes in patients who underwent arthroscopic partial meniscectomy with horizontal cleavage tear and without additional intraarticular knee pathology.

Methods A total of 37 patients complied with the study criteria. Patients were divided into two groups according to usage of bipolar radiofrequency. Patients were evaluated by using visual analog scale (VAS) and Tegner Lysholm knee scores at the end of the first year follow-up.

Results Twenty-two patients comprised the shaver-using group. Preoperative mean VAS score was 7.9 ± 0.8, and the Tegner Lysholm knee score was 49.6 ± 9.6. Fifteen patients comprised the bipolar radiofrequency-using group. Preoperative VAS score was 7.8 ± 0.9, and the Tegner Lysholm knee score was 52.2 ± 10.7. The mean VAS score was 1.2 ± 0.9, and the mean Tegner Lysholm knee score was 89.5 ± 8.1 in shaver used group at last follow-up. At the last postoperative follow-up, the mean VAS score was 1.1 ± 1, and the Tegner Lysholm knee score was 88.8 ± 7.3 in the bipolar radiofrequency-using group. No statistically significant differences between the VAS and Tegner Lysholm knee scores of the preoperative and postoperative controls of the two groups were observed (p≥0.05).

Conclusion Radiofrequency use has no effect on early clinical outcomes in the arthroscopic treatment of isolated medial meniscus posterior horn horizontal cleavage tears; we do not recommend its use.

Keywords: radiofrequency; horizontal cleavage tear; meniscus

INTRODUCTION

Horizontal cleavage tears in young people were first described in 1993 by Biedert et al. [1]. Horizontal cleavage tears have a traumatic or non-traumatic etiology during degeneration caused by disruption of the load distribution in the knee joint. Horizontal cleavage tears extend to the inferior surface of the meniscus [2].

Degenerative meniscus tears usually involve horizontal cleavage tears and are more common in middle-aged patients. The prevalence of horizontal cleavage tears increases with age [3]. A mechanical relationship between meniscus degeneration and knee osteoarthritis is believed to exist, but no consensus on the relationship between the structures of the cartilage and meniscus and the sequence of degeneration is yet available. Conservative treatments, arthroscopic meniscus sutures, and arthroscopic partial meniscectomy are performed in the treatment of horizontal cleavage tears [4].

Arthroscopic mechanical hand tools, motorized shavers, and bipolar radiofrequency are used in arthroscopic partial meniscectomy. The use of radiofrequency can cause cell death due to thermal effects on cartilage tissue. Allen et al. [5] found that cell death rates do not differ between debridement with punch and mechanical shaving and meniscus debridement using bipolar radiofrequency. The authors thus stated that bipolar radiofrequency does not damage the cartilage of joint surfaces and provides a smooth contour on the meniscus surface [5].

The aim of this study is to evaluate retrospectively the efficacy of radiofrequency on early clinical outcomes in patients who underwent arthroscopic partial meniscectomy with horizontal cleavage tear and without additional intraarticular knee pathology.

METHODS

This retrospective study was approved by the ethics board of Bahçeşehir University, Faculty of Medicine, (No. 2019-18/01) and conducted in accordance with the Declaration of Helsinki. Informed written consent was obtained from all patients included in the study.

A total of 218 patients who underwent knee arthroscopy in our clinic in 2018 were evaluated retrospectively in our study. The inclusion criteria were ages 20–50, detection of tears in
the posterior horn of the medial meniscus on preoperative magnetic resonance imaging, and detection of only horizontal cleavage tears in the posterior horn of the medial meniscus without any other intraarticular knee pathology during arthroscopy. Patients with visual analog scale (VAS) and Tegner Lysholm knee scores in their preoperative and postoperative follow-up files were included in the study. Patients who were under 20 and over 50 years of age, with inflammatory arthropathy, who had cartilage problems in the medial, lateral, or patellar femoral joints, who had lateral meniscus tear or anterior cruciate ligament injuries in addition to the horizontal cleavage tear in the medial meniscus, and those with trauma history were excluded from the study.

**Surgical technique**

Prophylaxis of the patients before surgery was performed with 1 g of cefazolin sodium. A tourniquet was applied to the extremity under general or spinal anesthesia. An anterolateral portal was created in all surgeries, and an anteromedial portal was created after diagnostic arthroscopy. First, the patellofemoral joint, lateral, and medial gutters were evaluated. The medial compartment medial meniscus, anterior cruciate ligament, lateral compartment, and lateral meniscus were then evaluated. Partial meniscectomy using appropriate angled punches was performed for patients who had horizontal cleavage tears in the posterior horn of the medial meniscus. During partial meniscectomy, the upper and lower flaps were excised by preserving the outer 50% of the meniscus. Meniscus contours were smoothed by using a shaver in some patients and bipolar radiofrequency in some patients. After the tourniquet was deflated, the portals were closed.

**Postoperative follow-up and patient data collection**

All patients underwent a postoperative physical therapy program and were evaluated using VAS and Tegner Lysholm knee scores at the end of the first year of follow-up [6]. The surgical and follow-up files of patients who underwent arthroscopy with a follow-up period of over one year were evaluated retrospectively. A total of 37 patients complied with the study criteria. When the patients' operations were evaluated, we determined that bipolar radiofrequency was not used during the arthroscopic partial meniscectomy of 22 patients. Bipolar radiofrequency was used during the arthroscopic partial meniscectomy of 15 patients. Patients were divided into two groups according to bipolar radiofrequency use.

**Statistical analysis**

The suitability of the data to a normal distribution was tested. Because the data were not normally distributed, pre- and postoperative VAS and Tegner Lysholm knee scores were analyzed by using the Wilcoxon test, which is a non-parametric version of the paired t-test. Differences in VAS and Tegner Lysholm knee scores between the bipolar radiofrequency-using and -non-using groups were also evaluated by the Mann–Whitney U test. A p value of < 0.05 was considered statistically significant at the 95% confidence interval.

**RESULTS**

Of the 37 patients who met the study criteria, 25 were male and 12 were female. The mean age of the patients was 38.6 ± 5.1 years. Patients included in our study mostly consisted of heavy workers. The lifestyle in Turkey was the main reason for younger average age for horizontal cleavage tears. Of the 22 patients without bipolar radiofrequency use during arthroscopic partial meniscectomy, 16 were male and six were female. The mean follow-up period was 13 ± 2.1 months in this group. The preoperative mean VAS score was 7.9 ± 0.8, and the Tegner Lysholm knee score was 49.6 ± 9.6. Ten of the 15 patients in the bipolar radiofrequency-using group were male; the rest were female. The mean follow-up period was 12 ± 9.4 months. In this group, the preoperative VAS score was 7.8 ± 0.9, and the Tegner Lysholm knee score was 52.2 ± 10.7. The mean VAS score was 1.2 ± 0.9, and the mean Tegner Lysholm knee score was 89.5 ± 8.1 in group which radiofrequency was not used at the last follow-up. At the last postoperative follow-up, the mean VAS score was 1.1 ± 1, and the Tegner Lysholm knee score was 88.8 ± 7.3 in the bipolar radiofrequency-using group (Table 1). Statistically significant differences in the VAS and Tegner Lysholm knee scores of the preoperative and postoperative final controls of both groups (p ≤ 0.05) were observed. No statistically significant differences in the VAS and Tegner Lysholm knee scores of the preoperative and postoperative controls of the two groups (p ≥ 0.05) were found.

**DISCUSSION**

Complex meniscal tears and cartilage defects are common among patients with early and advanced knee osteoarthritis. Pain and restriction of range of motion are also higher in this group of patients than in groups without knee osteoarthritis [7]. Major meniscus problems are more common in patients who need knee replacement than in those who do not need knee replacement [8, 9]. In particular, knees with macerations in the meniscus body and posteroomedial horn are more in need of knee arthroplasty than control knees [8]. Antony et al. [10] found that the meniscal changes, such as meniscus maceration and meniscus extrusion, are more likely to cause structural changes than meniscus signal increases and meniscus tears. The authors hence determined that meniscal maceration has
an effect on knee pain and knee osteoarthritis [10]. Horizontal cleavage tears are meniscus tears extending from the avascular zone to the vascular zone and considered degenerative meniscus tears [11]. Previous studies suggested that the earliest anatomic finding of knee osteoarthritis is a degenerative tear of the medial meniscus posterior horn. The aim of the present study is to exclude patients with chondral lesions and compare the treatment results of isolated medial meniscus horizontal cleavage tears by using bipolar radiofrequency and shaver.

Although patients with traumatic meniscus tears were not included in our study, Kim et al. [12] divided 40-year-old patients with horizontal cleavage tears into two groups according to the etiology of their meniscus tear as traumatic or degenerative meniscus tears. IKDC scores increased from 58.1 to 84.6 in the traumatic group and from 59.1 to 85.1 in the non-traumatic group. Lysholm scores increased from 61.1 to 85.5 in the traumatic group and from 62.2 to 86.1 in the non-traumatic group. No statistically significant difference was found between the two groups [12]. According to our results, a statistically significant increase in Lysholm scores exists between the preoperative and postoperative final controls.

Partial meniscectomy is recommended for the treatment of degenerative horizontal cleavage tears because these tears are located in the avascular region and, therefore, have lower healing potential compared with acute traumatic tears [13]. Koh et al. [14] found a decrease in contact area and increase in pressure on the medial compartment when they removed the inferior portion of horizontal cleavage tears in their study on cadaveric knees. The authors of that study found no further reductions in contact area or increases in pressure in medial femoral condyles with additional excision of the superior part of the horizontal cleavage tear [14]. Uquillas et al. [15] found that resection of the upper or lower flap in horizontal cleavage tears or resection of both flaps does not change the pressure on the contact surface. The authors thus recommended the preservation of the outer 50% of the medial meniscus in horizontal cleavage tears in the posterior horn of the medial meniscus [15]. In our study, we attempted to preserve 50% of the peripheral portion of the meniscus of patients who underwent partial meniscectomy, and we excised both flaps.

Another approach in the treatment of horizontal cleavage tears is meniscus repair. Arno et al. [16] found a 13% increase in contact pressure and 6% decrease in contact area as a result of horizontal cleavage tears in their cadaver study. The authors thus stated that horizontal cleavage tears may cause cartilage degeneration by causing few but statistically significant changes in tibiofemoral contact mechanics [16]. Beamer et al. [17] conducted a study on cadaver knees and determined that contact area and pressure on the contact area are close to normal values after the repair of horizontal cleavage tears with sutures. Moreover, the contact area decreased and the pressure on the contact area increased in knees treated with subtotal or partial meniscectomy [17]. Bilîères et al. [18] performed partial meniscectomy and open meniscus repair in 14 patients with degenerative horizontal cleavage tear and found a mean International Knee Documentation Committee score of 86.1 ± 10.9 after 8.5 years of follow-up. The authors also found the mean Knee Injury and Osteoarthritis Outcome Scores of 91.4 ± 7.5 for pain, 91.4 ± 10.2 for symptoms, 97.1 ± 4 for daily activity, 84.4 ± 20.7 for sports, and 84 ± 14.2 for the quality of life. The authors thus reported that repairing complex horizontal cleavage tears in young patients yields good subjective and objective results [18]. Despite these findings, however, negative results of horizontal cleavage tears after meniscus repair have been published. Biedert et al. [4], for example, compared four groups, including those conservatively treated, treated by meniscus suture, treated by meniscus suture using fibrin glue, and treated by partial meniscectomy. The scholars reported that the best short-term clinical results are obtained in the group treated by partial meniscectomy [4]. Shanmugaraj et al. [19] found that repair of horizontal cleavage tears has a higher complication rate than repair with partial meniscectomy. Since a meniscus repair group was not present in our study, our findings are somewhat limited.

Spahn et al. [20] performed arthroscopic debridement on patients with grade 3 chondrophyathy and degenerative tears of the medial meniscus. Here, cartilage debridement was performed by using radiofrequency in one group and shaving in another group. The authors reported that the clinical results of the radiofrequency group are better than those of the shaver group after one year of follow-up [20]. Spahn et al. [21] reported that the results of debridement with radiofrequency are better than those of mechanical debridement after four years.

Figueroa et al. [22] investigated thermal effects on the meniscus using bipolar radiofrequency and found cellular changes in deeper tissues with bipolar radiofrequency in elderly patients; the authors thus recommended that precautions be taken during the use of bipolar radiofrequency in elderly patients during meniscectomy and advocated the use of low intensities. Allen et al. [5] found no difference in cell death rate between meniscal debridement with bipolar radiofrequency and debridement with motorized shaver and punches. It was concluded that radiofrequency does not damage the joint surfaces under the meniscus.

Grana et al. [23] compared mechanical meniscectomy with meniscectomy using radiofrequency and found that cracks and clefts are formed on surfaces on which meniscectomy was performed mechanically; by comparison, the surfaces of menisci subjected to meniscectomy with radiofrequency were flatter and more homogeneous. The author further found that meniscectomy with radiofrequency offers more resistance than mechanical meniscectomy in static tests [23].

Vangsnes et al. [24] studied the effects of monopolar and bipolar radiofrequency devices on tissue during meniscectomy. No difference was detected between the two systems, and the use of radiofrequency factors, such as geometric shape of the probe, was reported to have an effect on the depth of thermal effect [24]. Studies showing the advantages of radiofrequency use and a low risk of osteonecrosis after use have been published. However, according to our findings, the results of partial meniscectomy using
radiofrequency and partial meniscectomy using shaver and punch are not significantly different.

CONCLUSION

We believe that radiofrequency use has no superior effect than mechanical debridement with motorized shaver and punch on early clinical outcomes in the arthroscopic treatment of isolated medial meniscus posterior horn horizontal cleavage tears in young adults. Usage of radiofrequency is high cost. Thus, we do not recommend its use.

Увод/Циљ
У делимичној артроскопској менискектомији користе се артроскопски механички ручни алати, моторизовани бријачи и биполарна радиофраквенција. Циљ ове студије је да се процени ефикасност радиофраквенције на раним клиничким исходима код болесника који су били подвргнути делимичној артроскопској менискектомији са хоризонталним расцепом и без додатне интраартикуларне патологије колена.
Методе
Укупно 37 болесника испунило је критеријуме студије. Болесници су подељени у две групе према коришћењу биполарне радиофраквенције. Оцењени су помоћу визуелне аналогне скале (ВАС) и Tegner Lysholm knee посle годину дана праћења.
Резултати
Двадесет два болесника су користиће шејвер. Преоперативни скор ВАС-а је био 7,9 ± 0,8, а скор Tegner Lysholm knee 52,2 ± 10,7. Петнаест болесника чинило је биполарну групу која користи радиофраквенцију. Преоперативни резултат ВАС-а био је 7,8 ± 0,9, а средњи скор Tegner Lysholm knee 52,2 ± 10,7. Просечан скор ВАС-а је био 1,2 ± 0,9, а средњи средњи скор Tegner Lysholm knee 89,5 ± 8,1 у групи која је користила шејвер приликом последње контроле. Током последње контроле средња вредност ВАС-а била је 1,1 ± 1, а средњи средњи Tegner Lysholm knee је био 88,8 ± 7,3 у групи која је користила биполарну радиофраквенцију. Нису примећене статистички значајне разлике између скорова ВАС-а и Tegner Lysholm knee преоперативне и постоперативне контроле две групе (p ≥ 0,05). Закључак
Коришћење радиофраквенције нема ефекта на рани клинички исход у артроскопском лечењу изолованог хоризонталног расцепа медијалног менисуса; не препоручујемо његову употребу.
Кључне речи: радиофраквенција; хоризонтални расцеп; менисус
