Accepted papers are articles in press that have gone through due peer review process and have been accepted for publication by the Editorial Board of the Serbian Archives of Medicine. They have not yet been copy edited and/or formatted in the publication house style, and the text may be changed before the final publication. Although accepted papers do not yet have all the accompanying bibliographic details available, they can already be cited using the year of online publication and the DOI, as follows: the author’s last name and initial of the first name, article title, journal title, online first publication month and year, and the DOI; e.g.: Petrović P, Jovanović J. The title of the article. Srp Arh Celok Lek. Online First, February 2017.

When the final article is assigned to volumes/issues of the journal, the Article in Press version will be removed and the final version will appear in the associated published volumes/issues of the journal. The date the article was made available online first will be carried over.

Surgical Treatment of Carotid Artery Aneurysm Associated with Kinking: A Case Report and Review of Literature

Хируршко лечење анеуризме каротидне артерије удружене са кинкингом: Приказ болесника и преглед литературе

SUMMARY

Introduction Extracranial carotid artery aneurysm is a rare clinical entity with potentially debilitating consequences. The aim of this work was to present a case of a large internal carotid artery (ICA) aneurysm combined with medial ICA kinking successfully treated by resection and end-to-end anastomosis. Case Outline A 34-year-old female was admitted to our hospital due to dizziness and frequent non-specific headaches. On admission routine echocardiography showed an aneurysm of the atrial septum. Multislice computed tomography (MSCT) of the supraaortic branches showed medial kinking of the right ICA with a 15 mm aneurysm localized on the vertex of the angulation. Kinking was present on left ICA as well, with small aneurysm of 5 mm in diameter. The right ICA aneurysm was resected and the artery was reconstructed with an end-to-end anastomosis. The postoperative course was uneventful and the patient was symptom free after one year follow-up. Conclusion Surgery of aneurysm and kinking of carotid artery in medial segment of ICA is possible and safe to perform. Keywords: carotid artery aneurysm; kinking; surgical treatment

INTRODUCTION

Extracranial carotid artery aneurysm is a rare clinical entity with potentially debilitating consequences [1]. According to the major referral centers they make 0.4-0.9% of all repaired aortic and peripheral artery aneurysms [1, 2].

Therefore, only a small number of reports in the literature describes internal carotid artery (ICA) aneurysm associated with kinking [3-7]. Our aim is to present a case of a large internal carotid artery aneurysm combined with medial ICA kinking successfully treated by resection an end-to-end anastomosis.

CASE REPORT

A 34-year-old female was admitted to our hospital due to dizziness and frequent non-specific headaches. Arterial hypertension, hyperlipidemia, smoking and positive family history were identified as risk factors for atherosclerosis. The patient denied any other chronic illnesses, previous surgery or trauma.
On admission routine echocardiography showed an aneurysm of the atrial septum and a potentially patent foramen ovale. Subsequent transesophageal echocardiography confirmed the presence of the aneurysm, but the presence of shunt between the atria was excluded.

Multislice computed tomography (MSCT) of the supraaortic branches showed medial kinking of the right ICA with a 15 mm aneurysm localized on the vertex of the angulation (Figure 1). Kinking was also present on the left ICA with a small aneurysm of 5 mm in diameter. Other supraaortic branches and intracranial arterial network had no significant lesions. In addition, computed tomography of the brain without contrast did not reveal any pathological findings.

The patient underwent surgery in general anesthesia. Carotid arteries were exposed through typical longitudinal incision on the right side of the neck. Aneurysm and the kinked segment of the ICA were dissected. The aneurysm was located approximately 5 centimeters from carotid bifurcation, and about 1.5 cm distally from hypoglossal nerve (Figure 2). After systemic heparin administration, carotid arteries were clamped (without shunt insertion), the aneurysm was resected and ICA was reconstructed with an end-to-end anastomosis (Figure 3). Clamping time was 7 minutes.
The resected aneurysm was sent for pathohistology, which showed that the arterial wall was irregularly thinned, with a discrete intimal layer and congestion in the adventitial layer.

On the second postoperative day the patient had a mild edema of the right hipopharynx, which was successfully treated with corticosteroids. There were no other complications in the immediate postoperative period. She was discharged from the hospital in good condition on the fourth postoperative day. After one year follow-up the patient was symptom free and Doppler ultrasound revealed normal findings on right carotid arteries.

**DISCUSSION**

Carotid artery aneurysm treatment accounts for only 1% to 1.5% of all surgery performed in treatment of extracranial cerebrovascular disease [1, 8]. The age of the patients vary from 26–82 years of age throughout the studies, and is typically related to the etiology of the disease [1].

Most authors report atherosclerosis as the most common cause of true extracranial ICA aneurysms. On the other hand pseudoaneurysms can be a result of trauma or infection, especially in younger population. There is also a subgroup of patients with pseudoaneurysms related to previous carotid endarterectomy with patch angioplasty [1, 2, 9, 10].

Carotid aneurysms are often identified by the presence of a pulsatile mass on the lateral side of the neck. Symptomatic ICA aneurysms usually give neurological symptoms, global in more cases than hemispheric. In addition, significant number of patients with larger aneurysms also have symptoms due to the compression of the surrounding structures. However prevention of complications like rupture, complete thrombosis of the aneurysm and brain embolisation resulting in an acute ischemic event is the main goal of treatment.

Treatment of carotid artery aneurysm comprises of surgical and endovascular approaches. In distant past, ligation of the common carotid artery was the treatment of choice, but had high rates of morbidity and mortality [11]. Later, various surgical techniques were developed including aneurysmectomy with primary/patch closure, resection of the aneurysm with primary anastomosis or grafting (both venous and synthetic) [12].

Recent systematic review identified 281 articles reporting carotid artery aneurysms from 1900 to July 2014 [10]. Although natural history of this disease is not understood well, the aneurysms seem to rupture rarely. Consequently, the focus of treatment was mainly the prevention of thromboembolic events. Most authors conducted surgical treatment with good long-term results, but with considerable incidence of cranial nerve damage. Endovascular approach also showed satisfying results, but with no mid- or long-term follow-up.

True prevalence of ICA kinking in general population is unknown. Several reports show that this condition is bilateral in 25-50% of the cases and that it is more common in women [13, 14]. The relationship between the degree of ICA kinking and neurologic symptoms is still unclear. Patients with tortuous carotid arteries are rarely symptomatic, but if so, they usually present with global
neurological symptomatology. In a randomized controlled trial, including patients with ICA kinks and coils with hemispheric neurological symptoms, authors showed significantly better results with surgical than with best medical treatment [13]. Changes in hemodynamics of the blood flow through the kinked ICA segment can mimic stenosis and can also influence changes in intimal layer of the arterial wall leading to ulcerations and predisposition for thrombosis.

We identified just a few cases in the literature concerning ICA aneurysms secondary to carotid artery kinks and coils, and to our knowledge none of them presented a case of such a young female patient [3, 4, 6, 7]. In our case, saccular aneurysm of the ICA was formed secondary to hemodynamically significant kinking of the vessel.

According to Welleewerd et al. [15, 16] carotid artery aneurysms can be histologically classified as degenerative and disective. Although our sample was not identically processed, it could be categorized as degenerative due to the variable thickness of the arterial wall and the absence of any intimal disruptions. However there were no inflammatory cells found in the sample, which differs from the majority of findings in the abovementioned study.

The incidental finding of atrial septal aneurysm without patent foramen ovale could have been important for our patient. Several studies linked this condition to cerebrovascular symptoms and recent strokes in patients with normal carotid arteries [15, 16]. Considering the age of the patient, presence of the ICA kinking bilaterally, and two separate entities resulting from the weakness of the cardiovascular wall structure, our opinion is that there might be a embryological background in these conditions.

In our case kinking and aneurysm were located well above mandible angle and cranial to hypoglossal nerve. Meticulous surgical technique and high approach to ICA were performed with the resection of posterior belly of digastric muscle. According to our previous experience with treatment of carotid artery aneurysms, the presence of kinking facilitates resection of the aneurysm with reconstruction of ICA by end-to-end anastomosis [17].

We showed that surgery of aneurysm and kinking of carotid artery in medial segment of ICA is possible and safe to perform. Detailed preoperative preparation, precise surgical technique and short clamping time all contributed to good final outcome.
